

Changes from the low-fi prototype to the implementation

- Precipitation is not shown on weekly panel (API does not provide it). Wind speed, along with daily low and high temperature for each day are shown instead
- Only 5 days are shown on the weekly view (down from 7), as the API does not provide more
- Only 5 days of GDD forecast are shown in the GDD view (down from 7), as the API does not provide more
- Location accurate to ~15km radius, slightly worse than our desired 5-10km radius. This is due to the density of Met Office locations provided by the API
- Notification checkboxes in the settings view don't actually do anything, since Swing doesn't provide the same notification functionality as we would want to use in the final product developed for a phone
